LAUNCHING A WEB SITE USING A PASSIVE TRANSPONDER

TECHNICAL FIELD OF THE INVENTION

This invention is related to method of triggering the automatic display of a web page of a server on a network in response to a user bringing a passive transponder in range of an activating transmitter/receiver system connected to a computer which is also disposed on the network.

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a Continuation-in-Part of U.S. patent application Ser. No. 09/378,221 entitled "METHOD AND APPARATUS FOR ACCESSING A REMOTE LOCATION BY SCANNING AN OPTICAL CODE" filed on Aug. 19, 1999, now U.S. Pat. No. 6,745,234, issued on Jun. 1, 2004, which is a Continuation-in-Part of the following two U.S. patent application Ser. No. 09/151,471 entitled "METHOD FOR INTERFACING SCANNED PRODUCT INFORMATION WITH A SOURCE FOR THE PRODUCT OVER A GLOBAL NETWORK," filed Sep. 11, 1998, now abandoned, and Ser. No. 09/151,530 entitled "METHOD FOR CONTROLLING A COMPUTER WITH AN AUDIO SIGNAL," filed on Sep. 11, 1998, now U.S. Pat. No. 6,098,106, issued on Aug. 1, 2000.

BACKGROUND OF THE INVENTION

With the growing numbers of computer users connecting to the "Internet," many companies are seeking the substantial commercial opportunities presented by such a large user base. For example, one technology which exists allows a television ("TV") signal to trigger a computer response in which the consumer will be guided to a personalized web page. The source of the triggering signal may be a TV, video tape recorder, or radio. For example, if a viewer is watching a TV program in which an advertiser offers viewer voting, the advertiser may transmit a unique signal within the television signal which controls a program known as a "browser" on the viewer's computer to automatically display the advertiser's web page. The viewer then simply makes a selection which is then transmitted back to the advertiser.

In order to provide the viewer with the capability of responding to a wide variety of companies using this technology, a database of company information and Uniform Resource Locator ("URL") codes is necessarily maintained in the viewer's computer, requiring continuous updates. URLs are short strings of data that identify resources on the Internet: documents, images, downloadable files, services, electronic mailboxes, and other resources. URLs make resources available under a variety of naming schemes and access methods such as HTTP, FTP, and Internet mail, addressable in the same simple way. URLs reduce the tedium of "login to this server, then issue this magic command . . ." down to a single click. The Internet uses URLs to specify the location of files on other servers. A URL includes the type of resource being accessed (e.g., Web, gopher, FTP), the address of the server, and the location of the file. The URL can point to any file on any networked computer. Current technology requires the viewer to perform periodic updates to obtain the most current URL database. This aspect of the current technology is cumbersome since the update process requires downloading information to the viewer's computer. Moreover, the likelihood for error in performing the update, and the

2

necessity of redoing the update in the event of a later computer crash, further complicates the process. Additionally, current technologies are limited in the number of companies which may be stored in the database. This is a significant limitation since world-wide access presented by the Internet and the increasing number of companies connecting to perform on-line E-commerce necessitates a large database.

A device is needed which facilitates easy access to network-based information to circumvent the technical knowledge required to find and retrieve such information using conventional means.

SUMMARY OF THE INVENTION

The present invention disclosed and claimed herein, in one aspect thereof, comprises a method of displaying a web page to a user. A triggering device having a unique code stored therein is providing to the user. The unique code is extracted from the triggering device with an activation system, the activation system disposed on a network. Location information associated with the unique code is retrieved from a database, the location information corresponding to a location of the web page on a remote location disposed on the network. In response to retrieving the location information, the activation system is connected to the remote location. The web page corresponding to the location information of the remote location is then presented to the user via the activation system.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention and the advantages thereof, reference is now made to the following description taken in conjunction with the accompanying Drawings in which:

FIG. 1 illustrates a block diagram of the preferred embodiment;

FIG. 2 illustrates the computer components employed in this embodiment;

FIG. 3 illustrates system interactions over a global network;

FIGS. 4a-4e illustrate the various message packets transmitted between the source PC and network servers used in the preferred embodiment; and

FIG. 5 is a flowchart depicting operation of the system according to the preferred embodiment.

FIG. 6 illustrates a flowchart of actions taken by the Advertiser Reference Server ("ARS") server;

FIG. 7 illustrates a flowchart of the interactive process between the source computer and ARS;

FIG. 8 illustrates a web browser page receiving the modified URL/advertiser product data according to the preferred embodiment;

FIG. 9 illustrates a simplified block diagram of the disclosed embodiment;

FIG. 10 illustrates a more detailed, simplified block diagram of the embodiment of FIG. 9;

FIG. 11 illustrates a diagrammatic view of a method for performing the routing operation;

DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIG. 1, there is illustrated a block diagram of a system for controlling a personal computer ("PC") 112 via an audio tone transmitted over a wireless system utilizing a TV. In the embodiment illustrated in FIG. 1, there is provided a transmission station 101 and a receive station 117 that are connected via a communication link 108. The transmission station 101 is comprised of a television program source 104, which is operable to generate a program in the form of a broadcast signal comprised of video and audio. This is transmitted via conventional techniques along channels in the appropriate frequencies. The program source is input to a mixing device 106, which mixing device is operable to mix in an audio signal. This audio signal is derived from an audio source 100 which comprises a coded audio signal which is then modulated onto a carrier which is combined with the television program source 104. This signal combining can be done at the audio level, or it can even be done at the RF level in the form of a different carrier. However, the preferred method is to merely sum the audio signal from the modulator 102 into the audio channel of the program that is generated by the television program source 104. The output thereof is provided from the mixing device 106 in the form of broadcast signal to an antenna 107, which transmits the information over the communication link 108 to an antenna 109 on the receive side.

On the receive side of the system, a conventional receiver 110, such as a television is provided. This television provides a speaker output which provides the user with an audible signal. This is typically associated with the program. However, the receiver 110 in the disclosed embodiment, also provides an audio output jack, this being the type RCA jack. This jack is utilized to provide an audio output signal on a line 113 which is represented by an audio signal 111. This line 113 provides all of the audio that is received over the communi-

cation link 108 to the PC 112 in the audio input port on the PC 112. However, it should be understood that, although a direct connection is illustrated from the receiver 110 to the PC 112, there actually could be a microphone pickup at the PC 112 which could pick the audio signal up. In the disclosed embodiment, the audio signal generated by the advertiser data input device 100 is audible to the human ear and, therefore, can be heard by the user. Therefore, no special filters are needed to provide this audio to the PC 112.

The PC 112 is operable to run programs thereon which typically are stored in a program file area 116. These programs can be any type of programs such as word processing programs, application programs, etc. In the disclosed embodiment, the program that is utilized in the system is what is referred to as a "browser." The PC 112 runs a browser program to facilitate the access of information on the network, for example, a global communication network known as the "Internet" or the World-Wide-Web ("Web"). The browser is a hypertext-linked application used for accessing information. Hypertext is a term used to describe a particular organization of information within a data processing system, and its presentation to a user. It exploits the computer's ability to link together information from a wide variety of sources to provide the user with the ability to explore a particular topic. The traditional style of presentation used in books employs an organization of the information which is imposed upon it by limitations of the medium, namely fixed sized, sequential paper pages. Hypertext systems, however, use a large number of units of text or other types of data such as image information, graphical information, video information, or sound information, which can vary in size. A collection of such units of information is termed a hypertext document, or where the hypertext documents employ information other than text, hypermedia documents. Multimedia communications may use the Hypertext Transfer Protocol ("HTTP"), and files or formatted data may use the Hypertext Markup Language ("HTML"). This formatting language provides for a mingling of text, graphics, sound, video, and hypertext links by "tagging" a text document using HTML. Data encoded using HTML is often referred to as an "HTML document," an "HTML page," or a "home page." These documents and other Internet resources may be accessed across the network by means of a network addressing scheme which uses a locator referred to as a Uniform Resource Locator ("URL"), for example, "http://www.digital.com."

The Internet is one of the most utilized networks for inter-connecting distributed computer systems and allows users of these computer systems to exchange data all over the world. Connected to the Internet are many private networks, for example, corporate or commercial networks. Standard protocols, such as the Transport Control Protocol ("TCP") and the Internet Protocol ("IP") provide a convenient method for communicating across these diverse networks. These protocols dictate how data are formatted and communicated. As a characteristic of the Internet, the protocols are layered in an IP stack. At higher levels of the IP stack, such as the application layer (where HTTP is employed), the user information is more readily visible, while at lower levels, such as the network level (where TCP/IP are used), the data can merely be observed as packets or a stream of rapidly moving digital signals. Superimposed on the Internet is a standard protocol interface for accessing Web resources, such as servers, files, Web pages, mail messages, and the like. One way that Web resources can be accessed is by browsers made by Netscape® and Microsoft Internet Explorer®.

Referring again now to FIG. 1, the user can load this program with the appropriate keystrokes such that a browser

5

window will be displayed on a display **118**. In one embodiment, the user can run the browser program on the PC **112** such that the browser window is displayed on the display **118**. While watching a preferred program, the user can also view display **118**. When an audio signal is received by the receiver **110** and the encoded information is contained therein that was input thereto by the advertiser, the PC **112** will then perform a number of operations. The first operation, according to the disclosed embodiment, is to extract the audio information within the received audio signal in the form of digital data, and then transmit this digital data to a defined location on the global communication network via a modem connection **114**. This connection will be described hereinbelow. This information will be relayed to a proprietary location and the instructions sent back to the PC **112** as to the location of the advertiser associated with the code, and the PC **112** will then effect a communication link to that location such that the user can view on the display **118** information that the advertiser, by the fact of putting the tone onto the broadcast channel, desires the viewer to view. This information can be in the form of interactive programs, data files, etc. In one example, when an advertisement appears on the television, the tone can be generated and then additional data displayed on the display **118**. Additionally, a streaming video program could be played on the PC received over the network, which streaming video program is actually longer than the advertising segment on the broadcast. Another example would be a sports game that would broadcast the tone in order to allow a user access to information that is not available over the broadcast network, such as additional statistics associated with the sports program, etc.

By utilizing the system described herein with respect to the disclosed embodiment of FIG. 1, an advertiser is allowed the ability to control a user's PC **112** through the use of tones embedded within a program audio signal. As will be described hereinbelow, the disclosed embodiment utilizes particular routing information stored in the PC **112** which allows the encoded information in the received audio signal to route this information to a desired location on the network, and then allow other routing information to be returned to the PC **112** for control thereof to route the PC **112** to the appropriate location associated with that code.

Referring now to FIG. 2, there is illustrated a computer **204**, similar to computer **112**, connected to display information on display **118**. The computer **204** comprises an internal audio or "sound" card **206** for receiving the transmitted audio signal through receive antenna **109** and receiver **110**. The sound card **206** typically contains analog-to-digital circuitry for converting the analog audio signal into a digital signal. The digital signal may then be more easily manipulated by software programs. The receiver **110** separates the audio signal from the video signal. A special trigger signal located within the transmitted advertiser audio signal triggers proprietary software running on the computer **204** which launches a communication application, in this particular embodiment, the web browser application located on the PC **204**. Coded advertiser information contained within the audio signal is then extracted and appended with the address of a proprietary server located on the communication network. The remote server address is in the form of a URL.

This appended data, in addition to other control codes, is inserted directly into the web browser application for automatic routing to the communication network. The web browser running on PC **204**, and communicating to the network with an internal modem **208**, in this embodiment, transmits the advertiser information to the remote server. The remote server cross-references the advertiser product infor-

6

mation to the address of the advertiser server located on the network. The address of the advertiser server is routed back through the PC **204** web browser to the advertiser server. The advertiser product information is returned to PC **204** to be presented to the viewer on display **118**. In this particular embodiment, the particular advertiser product information displayed is contained within the advertiser's web page **212**. As mentioned above, the audio signal is audible to the human ear. Therefore the audio signal, as emitted from the TV speakers, may be input to the sound card **206** via a microphone. Furthermore, the audio signal need not be a real-time broadcast, but may be on video tapes, CDs, DVD, or other media which may be displayed at a later date. With the imminent implementation of high definition digital television, the audio signal output from the TV may also be digital. Therefore, direct input into a sound card for A/D purposes may not be necessary, but alternative interfacing techniques to accommodate digital-to-digital signal formats would apply.

Referring now to FIG. 3, there is illustrated a source PC **302**, similar to PCs **204** and **112**, connected to a global communication network (GCN) **306** through an interface **304**. In this embodiment, the audio signal **111** is received by PC **302** through its sound card **206**. The audio signal **111** comprises a trigger signal which triggers proprietary software into launching a web browser application residing on the PC **302**. The audio signal **111** also comprises advertiser product information which is extracted and appended with URL information of an Advertiser Reference Server ("ARS") **308**. The ARS **308** is a system disposed on the network **306** that is defined as the location to which data in the audio signal **111** is to be routed. As such, data in the audio signal **111** will always be routed to the ARS **308**, since a URL is unique on the GCN **306**. Connected to the ARS **308** is a database **310** of product codes and associated manufacturer URLs. The database **310** undergoes a continual update process which is transparent to the user. As companies sign-on, i.e., subscribe to this technology, manufacturer and product information are added to the database **310** without interrupting operation of the source PC **302** with frequent updates. When the advertiser server address URL is obtained from the ARS database **310**, it and the request for the particular advertiser product information is automatically routed back through the web browser on PC **302**, over to the respective advertiser server for retrieval of the advertiser product information to the PC **302**. Additionally, although the disclosed invention discusses a global communication network, the system is also applicable to LANs, WANs, and peer-to-peer network configurations. It should be noted that the disclosed architecture is not limited to a single source PC **302**, but may comprise a plurality of source PCs, e.g., PC **300** and PC **303**. Moreover, a plurality of ARS **308** systems and advertiser servers **312** may be implemented, e.g., ARS **314**, and advertiser server A **316**, respectively.

The information transactions, in general, which occur between the networked systems of this embodiment, over the communication network, are the following. The web browser running on source PC **302** transmits a message packet to the ARS **308** over Path "A." The ARS **308** decodes the message packet and performs a cross-reference function with product information extracted from the received message packet to obtain the address of an advertiser server **312**. A new message packet is assembled comprising the advertiser server **312** address, and sent back to the source PC **302** over Path "B." A "handoff" operation is performed whereby the source PC **302** browser simply reroutes the information on to the advertiser server **312** over Path "C," with the appropriate source and destination address appended. The advertiser server **312** receives and decodes the message packet. The request-for-

advertiser-product-information is extracted and the advertiser **312** retrieves the requested information from its database for transmission back to the source PC **302** over Path "D." The source PC **302** then processes the information, i.e., for display to the viewer. The optional Path "E" is discussed hereinbelow. It should be noted that the disclosed methods are not limited to only browser communication applications, but may accommodate, with sufficient modifications by one skilled in the art, other communication applications used to transmit information over the Internet or communication network.

Referring now to FIG. **4a**, the message packet **400** sent from the source PC **302** to ARS **308** via Path "A" comprises several fields. One field comprises the URL of the ARS **308** which indicates where the message packet is to be sent. Another field comprises the advertiser product code or other information derived from the audio signal **111**, and any additional overhead information required for a given transaction. The product code provides a link to the address of the advertiser server **312**, located in the database **310**. Yet another field comprises the network address of the source PC **302**. In general, network transmissions are effected in packets of information, each packet providing a destination address, a source address, and data. These packets vary depending upon the network transmission protocol utilized for communication. Although the protocols utilized in the disclosed embodiment are of a conventional protocol suite commonly known as TCP/IP, it should be understood that any protocols providing the similar basic functions can be used, with the primary requirement that a browser can forward the routing information to the desired URL in response to keystrokes being input to a PC. Within the context of this disclosure, "message packet" shall refer to and comprise the destination URL, product information, and source address, even though more than a single packet must be transmitted to effect such a transmission.

Upon receipt of the message packet **400** from source PC **302**, ARS **308** processes the information in accordance with instructions embedded in the overhead information. The ARS **308** specifically will extract the product code information from the received packet **400** and, once extracted, will then decode this product code information. Once decoded, this information is then compared with data contained within the ARS advertiser database **310** to determine if there is a "hit." If there is no "hit" indicating a match, then information is returned to the browser indicating such. If there is a "hit," a packet **402** is assembled which comprises the address of the source PC **302**, and information instructing the source PC **302** as to how to access, directly in a "handoff" operation, another location on the network, that of an advertiser server **312**. This type of construction is relatively conventional with browsers such as Netscape® and Microsoft Internet Explorer® and, rather than displaying information from the ARS **308**, the source PC **302** can then access the advertiser server **312**. The ARS **308** transmits the packet **402** back to source PC **302** over Path "B." Referring now to FIG. **4b**, the message packet **402** comprises the address of the source PC **302**, the URL of the advertiser server **312** embedded within instructional code, and the URL of the ARS **308**.

Upon receipt of the message packet **402** by the source PC **302**, the message packet **402** is disassembled to obtain pertinent routing information for assembly of a new message packet **404**. The web browser running on source PC **302** is now directed to obtain, over Path "C," the product information relevant to the particular advertiser server **312** location information embedded in message packet **404**. Referring now to FIG. **4c**, the message packet **404** for this transaction com-

prises the URL of the advertiser server **312**, the request-for-product-information data, and the address of the source PC **302**.

Upon receipt of the message packet **404** from source PC **302**, advertiser server **312** disassembles the message packet **404** to obtain the request-for-product-information data. The advertiser server **312** then retrieves the particular product information from its database, and transmits it over Path "D" back to the source PC **302**. Referring now to FIG. **4d**, the message packet **406** for this particular transaction comprises the address of the source PC **302**, the requested information, and the URL of the advertiser server **312**.

Optionally, the ARS **308** may make a direct request for product information over Path "E" to advertiser server **312**. In this mode, the ARS **308** sends information to the advertiser server **312** instructing it to contact the source PC **302**. This, however, is unconventional and requires more complex software control. The message packet **408** for this transaction is illustrated in FIG. **4e**, which comprises the URL of the advertiser server **312**, the request-for-product-information data, and the address of the source PC **302**. Since product information is not being returned to the ARS **308**, but directly to the source PC **302**, the message packet **408** requires the return address to be that of the source PC **302**. The product information is then passed directly to PC **302** over Path "D."

Referring now to FIG. **5**, the method for detecting and obtaining product information is as follows. In decision block **500**, a proprietary application running resident on a source computer PC **302** (similar to PC **204**) monitors the audio input for a special trigger signal. Upon detection of the trigger signal, data following the trigger signal is decoded for further processing, in function block **502**. In function block **504**, the data is buffered for further manipulation. In decision block **506**, a determination is made as to whether the data can be properly authenticated. If not, program flow continues through the "N" signal to function block **520** where the data is discarded. In function block **522**, the program then signals for a retransmission of the data. The system then waits for the next trigger signal, in decision block **500**. If properly authenticated in decision block **506**, program flow continues through the "Y" signal path where the data is then used to launch the web browser application, as indicated in function block **508**. In function block **510**, the web browser receives the URL data, which is then automatically routed through the computer modem **208** to the network interface **304** and ultimately to the network **306**. In function block **514**, the ARS **308** responds by returning the URL of advertiser server **312** to the PC **302**. In function block **516**, the web browser running on the source PC **302**, receives the advertiser URL information from the ARS **308**, and transmits the URL for the product file to the advertiser server **312**. In block **518**, the advertiser server **312** responds by sending the product information to the source PC **302** for processing. The user may obtain the benefits of this architecture by simply downloading the proprietary software over the network. Other methods for obtaining the software are well-known; for example, by CD, diskette, or pre-loaded hard drives.

Referring now to FIG. **6**, there is illustrated a flowchart of the process the ARS **308** may undergo when receiving the message packet **400** from the source PC **302**. In decision block **600**, the ARS **308** checks for the receipt of the message packet **400**. If a message packet **400** is not received, program flow moves along the "N" path to continue waiting for the message. If the message packet **400** is received, program flow continues along path "Y" for message processing. Upon receipt of the message packet **400**, in function block **602**, the ARS **308** decodes the message packet **400**. The product code

is then extracted independently in function block 604 in preparation for matching the product code with the appropriate advertiser server address located in the database 310. In function block 606, the product code is then used with a lookup table to retrieve the advertiser server 312 URL of the respective product information contained in the audio signal data. In function block 608, the ARS 308 then assembles message packet 402 for transmission back to the source PC 302. Function block 610 indicates the process of sending the message packet 402 back to the source PC 302 over Path "B."

Referring now to FIG. 7, there is illustrated a flowchart of the interactive processes between the source PC 302 and the advertiser server 312. In function block 700, the source PC 302 receives the message packet 402 back from the ARS 308 and begins to decode the packet 402. In function block 702, the URL of the advertiser product information is extracted from the message packet 402 and saved for insertion into the message packet 404 to the advertiser server 312. The message packet 404 is then assembled and sent by the source PC 302 over Path "C" to the advertiser server 312, in function block 704. While the source PC 302 waits, in function block 706, the advertiser server 312 receives the message packet 404 from the source PC 302, in function block 708, and disassembles it. The product information location is then extracted from the message packet 404 in function block 710. The particular product information is retrieved from the advertiser server 312 database for transmission back to the source PC 302. In function block 712, the product information is assembled into message packet 406 and then transmitted back to the source PC 302 over Path "D." Returning to the source PC 302 in function block 714, the advertiser product information contained in the message packet 406 received from the advertiser server 312, is then extracted and processed in function block 716.

Referring now to FIG. 8, after receipt of a trigger signal, a web browser application on a source PC 302 is automatically launched and computer display 800 presents a browser page 802. Proprietary software running on the source PC 302 processes the audio signal data after being digitized through the sound card 206. The software appropriately prepares the data for insertion directly into the web browser by extracting the product information code and appending keystroke data to this information. First, a URL page 804 is opened in response to a Ctrl-O command added by the proprietary software as the first character string. Opening URL page 804 automatically positions the cursor in a field 806 where additional keystroke data following the Ctrl-O command will be inserted. After URL page 804 is opened, the hypertext protocol preamble http:// is inserted into the field 806. Next, URL information associated with the location of the ARS 308 is inserted into field 806. Following the ARS 308 URL data are the characters /? to allow entry of variables immediately following the /? characters. In this embodiment, the variable following is the product information code received in the audio signal. The product code information also provides the cross-reference information for obtaining the advertiser URL from the ARS database 310. Next, a carriage return is added to send the URL/product data and close the window 804. After the message packet 400 is transmitted to the ARS 308 from the source PC 302, transactions from the ARS 308, to the source PC 302, to the advertiser server 312, and back to the source PC 302, occur quickly and are transparent to the viewer. At this point, the next information the viewer sees is the product information which was received from the advertiser server 312.

Referring now to FIG. 9, there is illustrated a block diagram of a more simplified embodiment. In this embodiment, a video source 902 is provided which is operable to provide an

audio output on an audio cable 901 which provides routing information referred to by reference numeral 904. The routing information 904 is basically information contained within the audio signal. This is an encoded or embedded signal. The important aspect of the routing information 904 is that it is automatically output in realtime as a function of the broadcast of the video program received over the video source 902. Therefore, whenever the program is being broadcast in realtime to the user 908, the routing information 904 will be output whenever the producer of the video desires it to be produced. It should be understood that the box 902 representing the video source could be any type of media that will result in the routing information being output. This could be a cassette player, a DVD player, an audio cassette, a CD ROM or any such media. It is only important that this is a program that the producer develops which the user 908 watches in a continuous or a streaming manner. Embedded within that program, at a desired point selected by the producer, the routing information 904 is output.

The audio information is then routed to a PC 906, which is similar to the PC 112 in FIG. 1. A user 908 is interfaced with the PC to receive information thereof, the PC 906 having associated therewith a display (not shown). The PC 906 is interfaced with a network 910, similar to the network 306 in FIG. 3. This network 910 has multiple nodes thereon, one of which is the PC 906, and another of which is represented by a network node 912 which represents remote information. The object of the present embodiment is to access remote information for display to the user 908 by the act of transmitting from the video program in block 902 the routing information 904. This routing information 904 is utilized to allow the PC 906 which has a network "browser" running thereon to "fetch" the remote information at the node 912 over the network 910 for display to the user 908. This routing information 904 is in the form of an embedded code within the audio signal, as was described hereinabove.

Referring now to FIG. 10, there is illustrated a more detailed block diagram of the embodiment of FIG. 9. In this embodiment, the PC 906 is split up into a couple of nodes, a first PC 1002 and a second PC 1004. The PC 1002 resides at the node associated with the user 908, and the PC 1004 resides at another node. The PC 1004 represents the ARS 308 of FIG. 3. The PC 1004 has a database 1006 associated therewith, which is basically the advertiser database 310. Therefore, there are three nodes on the network 910 necessary to implement the disclosed embodiment, the PC 1002, the PC 1004 and the remote information node 912. The routing information 904 is utilized by the PC 1002 for routing to the PC 1004 to determine the location of the remote information node 912 on the network 910. This is returned to the PC 1002 and a connection made directly with the remote information node 912 and the information retrieved therefrom to the user 908. The routing information 904 basically constitutes primary routing information.

Referring now to FIG. 11, there is illustrated a diagrammatic view of how the network packet is formed for sending the primary routing information to the PC 1004. In general, the primary routing information occupies a single field which primary routing information is then assembled into a data packet with the secondary routing information for transfer to the network 910. This is described hereinabove in detail.

Referring now to FIG. 12, there is illustrated an alternate embodiment to that of FIG. 9. In this embodiment, the video source 902 has associated therewith an optical region 1202, which optical region 1202 has disposed therein an embedded video code. This embedded video code could be relatively complex or as simple as a grid of dark and white regions, each

11

region in the grid able to have a dark color for a logic "1" or a white region for a logic "0." This will allow a digital value to be disposed within the optical region 1202. A sensor 1204 can then be provided for sensing this video code. In the example above, this would merely require an array of optical detectors, one for each region in the grid to determine whether this is a logic "1" or a logic "0" state. One of the sensed video is then output to the PC 906 for processing thereof to determine the information contained therein, which information contained therein constitutes the primary routing information 904. Thereafter, it is processed as described hereinabove with reference to FIG. 9.

Referring now to FIG. 13, there is illustrated a block diagram for an embodiment wherein a user's profile can be forwarded to the original subscriber or manufacturer. The PC 906 has associated therewith a profile database 1302, which profile database 1302 is operable to store a profile of the user 908. This profile is created when the program, after initial installation, requests profile information to be input in order to activate the program. In addition to the profile, there is also a unique ID that is provided to the user 908 in association with the browser program that runs on the PC 906. This is stored in a storage location represented by a block 1304. This ID 1304 is accessible by a remote location as a "cookie" which is information that is stored in the PC 906 in an accessible location, which accessible location is actually accessible by the remote program running on a remote node.

The ARS 308, which basically constitutes the PC 1004 of FIG. 10, is operable to have associated therewith a profile database 1308, which profile database 1308 is operable to store profiles for all of the users. The profile database 1308 is a combination of the stored in profile database 1302 for all of the PCs 906 that are attachable to the system. This is to be distinguished from information stored in the database 310 of the ARS 308, the advertiser's database, which contains intermediate destination tables. When the routing information in the primary routing information 904 is forwarded to the ARS 308 and extracted from the original data packet, the lookup procedure described hereinabove can then be performed to determine where this information is to be routed. The profile database 1302 is then utilized for each transaction, wherein each transaction in the form of the routing information received from the primary routing information 904 is compared to the destination tables of database 310 to determine what manufacturer is associated therewith.

The associated ID 1304 that is transmitted along with the routing information in primary routing information 904 is then compared with the profile database 1308 to determine if a profile associated therewith is available. This information is stored in a transaction database 1310 such that, at a later time, for each routing code received in the form of the information in primary routing information 904, there will be associated therewith the IDs 1304 of each of the PCs 906. The associated profiles in database 1308, which are stored in association with IDs 1304, can then be assembled and transmitted to a subscriber as referenced by a subscriber node 1312 on the network 910. The ARS 308 can do this in two modes, a realtime mode or a non-realtime mode. In a realtime mode, each time a PC 906 accesses the advertiser database 310, that user's profile information is uploaded to the subscriber node 1312. At the same time, billing information is generated for that subscriber 1312 which is stored in a billing database 1316. Therefore, the ARS 308 has the ability to inform the subscriber 1312 of each transaction, bill for those transactions, and also provide to the subscriber 1312 profile information regarding who is accessing the particular product advertisement having associated therewith the routing information

12

field 904 for a particular routing code as described hereinabove. This information, once assembled, can then be transmitted to the subscriber 1312 and also be reflected in billing information and stored in the billing information database 1316.

Referring now to FIG. 14, there is illustrated a flowchart depicting the operation for storing the profile for the user. The program is initiated in a block 1402 and then proceeds to a function block 1404, wherein the system will prompt for the profile upon initiation of the system. This initiation is a function that is set to activate whenever the user initially loads the software that he or she is provided. The purpose for this is to create, in addition to the setup information, a user profile. Once the user is prompted for this, then the program will flow to a decision block 1406 to determine whether the user provides basic or detailed information. This is selectable by the user. If selecting basic, the program will flow to a function block 1408 wherein the user will enter basic information such as name and serial number and possibly an address. However, to provide some incentive to the user to enter more information, the original prompt in function block 1404 would have offers for such things as coupons, discounts, etc., if the user will enter additional information. If the user selects this option, the program flows from the decision block 1406 to a function block 1410. In the function block 1410, the user is prompted to enter specific information such as job, income level, general family history, demographic information and more. There can be any amount of information collected in this particular function block.

Once all of the information is collected, in either the basic mode or the more specific mode, the program will then flow to a function block 1412 where this information is stored locally. The program then flows to a decision block 1414 to then go on-line to the host or the ARS 308. In general, the user is prompted to determine whether he or she wants to send this information to the host at the present time or to send it later. If he or she selects the "later" option, the program will flow to a function block 1415 to prompt the user at a later time to send the information. In the disclosed embodiment, the user will not be able to utilize the software until the profile information is sent to the host. Therefore, the user may have to activate this at a later time in order to connect with the host.

If the user has selected the option to upload the profile information to the host, the program will flow to the function block 1416 to initiate the connect process and then to a decision block 1418 to determine if the connection has been made. If not, the program will flow along a "N" path to a decision block 1420 which will timeout to an error block 1422 or back to the input of the connect decision block 1418. The program, once connected, will then flow along a "Y" path from decision block 1418 to a function block 1428 to send the profile information with the ID of the computer or user to the host. The ID is basically, as described hereinabove, a "cookie" in the computer which is accessed by the program when transmitting to the host. The program will then flow to a function block 1430 to activate the program such that it, at later time, can operate without requiring all of the setup information. In general, all of the operation of this flowchart is performed with a "wizard" which steps the user through the setup process. Once complete, the program will flow to a Done block 1432.

Referring now to FIG. 15, there is illustrated a flowchart depicting the operation of the host when receiving a transaction. The program is initiated at a Start block 1502 and then proceeds to decision block 1504, wherein it is determined whether the system has received a routing request, i.e., the routing information 904 in the form of a tone, etc., embedded

13

in the audio signal, as described hereinabove with respect to FIG. 9. The program will loop back around to the input of decision block 1504 until the routing request has been received. At this time, the program will flow along the "Y" path to a function block 1506 to receive the primary routing information and the user ID. Essentially, this primary routing information is extracted from the audio tone, in addition to the user ID. The program then flows to a function block 1508 to lookup the manufacturer URL that corresponds to the received primary routing information and then return the necessary command information to the originating PC 108 in order to allow that PC 108 to connect to the destination associated with the primary routing information. Thereafter, the program will flow to a function block 1510 to update the transaction database 1310 for the current transaction. In general, the routing information 904 will be stored as a single field with the associated IDs. The profile database 1308, as described hereinabove, has associated therewith detailed profiles of each user on the system that has activated their software in association with their ID. Since the ID was sent in association with the routing information, what is stored in the transaction database 1310 is the routing code, in association with all of the IDs transmitted to the system in association with that particular routing code. Once this transaction database 1310 has been updated, as described hereinabove, the transactions can be transferred back to the subscriber at node 312 with the detailed profile information from the profile database 1308.

The profile information can be transmitted back to the subscriber or manufacturer at the node 312 in realtime or non-realtime. A decision block 1512 is provided for this, which determines if the delivery is realtime. If realtime, the program will flow along a "Y" path to a function block 1514 wherein the information will be immediately forwarded to the manufacturer or subscriber. The program will then flow to a function block 1516 wherein the billing for that particular manufacturer or subscriber will be updated in the billing database 1316. The program will then flow into an End block 1518. If it was non-realtime, the program moves along the "N" path to a function block 1520 wherein it is set for a later delivery and it is accrued in the transaction database 1310. In any event, the transaction database 1310 will accrue all information associated with a particular routing code.

With a realtime transaction, it is possible for a manufacturer to place an advertisement in a magazine or to place a product on a shelf at a particular time. The manufacturer can thereafter monitor the times when either the advertisements are or the products are purchased. Of course, they must be scanned into a computer which will provide some delay. However, the manufacturer can gain a very current view of how a product is moving. For example, if a cola manufacturer were to provide a promotional advertisement on, for example, television, indicating that a new cola was going to be placed on the shelf and that the first 1000 purchasers, for example, scanning their code into the network would receive some benefit, such as a chance to win a trip to some famous resort in Florida or some other incentive, the manufacturer would have a very good idea as to how well the advertisement was received. Further, the advertiser would know where the receptive markets were. If this advertiser, for example, had placed the television advertisement in ten cities and received overwhelming response from one city, but very poor response from another city, he would then have some inclination to believe that either one poor-response city was not a good market or that the advertising medium he had chosen was very poor. Since the advertiser can obtain a relatively instant response and also content with that response as to the demo-

14

graphics of the responder, very important information can be obtained in a relatively short time.

It should be noted that the disclosed embodiment is not limited to a single source PC 302, but may encompass a large number of source computers connected over a global communication network. Additionally, the embodiment is not limited to a single ARS 308 or a single advertiser server 312, but may include a plurality of ARS and advertiser systems, indicated by the addition of ARS 314 and advertiser server A 316, respectively. It should also be noted that this embodiment is not limited only to global communication networks, but also may be used with LAN, WAN, and peer-to-peer configurations.

It should also be noted that the disclosed embodiment is not limited to a personal computer, but is also applicable to, for example, a Network Computer ("NetPC"), a scaled-down version of the PC, or any system which accommodates user interaction and interfaces to information resources.

One typical application of the above noted technique is for providing a triggering event during a program, such as a sport event. In a first example, this may be generated an advertiser. One could imagine that, due to the cost of advertisements in a high profile sports program, there is a desire to utilize this time wisely. If, for example, an advertiser contracted for 15 seconds worth of advertising time, they could insert within their program a tone containing the routing information. This routing information can then be output to the user PC 302 which will cause the user PC 302 to, via the network, obtain information from a remote location typically controlled by the advertiser. This could be in the form of an advertisement of a length longer than that contracted for. Further, this could be an interactive type of advertisement. An important aspect to the type of interaction between the actual broadcast program with the embedded routing information and the manufacturer's site is the fact that there is provided information as to the user PC 302 and a profile of the user themselves. Therefore, an advertiser can actually gain realtime information as to the number of individuals that are watching their particular advertisement and also information as to the background of those individuals, profile information, etc. This can be a very valuable asset to an advertiser.

In another example, the producer of the program, whether it be an on-air program, a program embedded in a video tape, CD-ROM, DVD, or a cassette, can allow the user to automatically access additional information that is not displayed on the screen. For example, in a sporting event, various statistics can be provided to the user from a remote location, merely by the viewer watching the program. When these statistics are provided, the advertiser can be provided with profile information and background information regarding the user. This can be important when, for example, the user may record a sports program. If the manufacturer sees that this program routing code is being output from some device at a time later than the actual broadcast itself, this allows the advertisers to actually see that their program is still being used and also what type of individual is using it. Alternatively, the broadcaster could determine the same and actually bill the advertiser an additional sum for a later broadcast. This is all due to the fact that the routing information automatically, through a PC and a network, will provide an indication to the advertiser the time at which the actual information was broadcast.

The different type of medium that can be utilized with the above embodiment are such things as advertisements, which are discussed hereinabove, contests, games, news programs, education, coupon promotional programs, demonstration media (demos), and photographs, all of which can be broadcast on a private site or a public site. This all will provide the

15

ability to allow realtime interface with the network and the remote location for obtaining the routed information and also allow for realtime billing and accounting.

Referring now to FIG. 16, there is illustrated a general block diagram of a disclosed embodiment. A keystroke automator (KA) 1600 is provided by a keystroke automator distributor to customers and is associated with that distributor via a KA ID stored therein. The KA 1600 is operable to read machine-resolvable code (MRC) (e.g., a bar code). The KA 1600 is either sold or freely distributed to customers for use with their personal computing systems. Since more and more products are being sold using MRCs, it can be appreciated that a user having the keystroke automator 1600 can scan MRCs of a multitude of products in order to obtain more information. Information about these products can be made immediately available to the user from the manufacturer for presentation by the user's computer 302. Beyond simply displaying information about the product in which the user is interested, the keystroke automator distributor may include additional advertising information for display to the user such as information about other promotions or products provided or sold by the keystroke automator distributor. Similarly, advertisers may provide catalogs of advertisements or information in newspapers or periodicals where the user simply scans the MRC associated with the advertisement using the keystroke automator 1600 to obtain further information. There is provided a paper source 1602 having contained thereon an advertisement 1604 and an associated MRC 1606. (Note that the disclosed concept is not limited to scanning of MRCs 1606 from paper sources 1602, but is also operable to scan a MRC 1606 on the product itself. Also, the keystroke automator 1600 can be any type of device that will scan any type of image having information encoded therein.)

After obtaining the keystroke automator 1600 from the keystroke automator distributor, the user connects the keystroke automator 1600 to their PC 302. During a scanning operation, keystroke automator 1600 reads MRC data 1606 and the keystroke automator ID into a "wedge" interface 1608 for conversion into keyboard data, which keyboard data is passed therefrom into the keyboard input port of PC 302. The importance of the keystroke automator ID will be discussed in more detail hereinbelow.

The wedge interface 1608 is simply an interface box containing circuitry that accommodates inputs from both the keystroke automator 1600 and a computer keyboard 1610. This merely allows the information scanned by the keystroke automator 1600 to be input into the PC 302. In the disclosed embodiment, the wedge interface 1608 will convert any information. The data output from the keystroke automator 1600 is passed into the wedge interface 1608 for conversion into keyboard data which is readily recognizable by the PC 302. Therefore, the keystroke automator 1600 is not required to be connected to a separate port on the PC 302. This data is recognized as a sequence of keystrokes. However, the output of the keystroke automator 1600 can be input in any manner compatible with the PC 302. When not receiving keystroke automator data, the wedge interface 1608 simply acts as a pass-through device for keyboard data from the keyboard 1610. In any case, the information is ultimately processed by a processor in the PC 302 and can be presented to the user on a display 1612. The wedge interface 1608 is operable to provide a decoding function for the MRC 1606 and conversion thereof to keystroke input data.

In operation, the product code of a product is provided in the form of a MRC 1606. This MRC 1606 is the "link" to a product. The disclosed embodiment is operable to connect that product information contained in the MRC 1606 with a

16

web page of the manufacturer of that product by utilizing the MRC 1606 as the product "identifier." The program operating on the PC 302 provides routing information to the ARS 308 after launching the browser on the PC 302 and connecting to the ARS 308 over the GCN 306, which ARS 308 then performs the necessary steps to cause the browser to connect to the manufacturer web site, while also providing for an accounting step, as will be described in more detail hereinbelow.

The MRC 1606 by itself is incompatible with any kind of network for the purposes of communication therewith. It is primarily provided for a retail-type setting. Therefore, the information contained in the MRC 1606, by itself, does not allow for anything other than identification of a product, assuming that one has a database 1614 containing information as to a correlation between the product and the MRC 1606.

The wedge interface 1608 is operable to decode the MRC 1606 to extract the encoded information therein, and append to that decoded MRC information relating to an ID for the keystroke automator 1600. This information is then forwarded to the ARS 308 by the resident program in the PC 302. This is facilitated by intermediate routing information stored in the program indicating to which node on the GCN 306 the scanned MRC information is to be sent, i.e., to the ARS 308. It is important to note that the information in the MRC 1606 must be converted from its optical image to numerical values which are then ultimately input to the keyboard input port of PC 302 and converted into data compatible with communication software residing on the PC 302 (in this case, HTML language for insertion into a browser program). When the scanned information is input to the PC 302, the resident program launches the browser program and then assembles a communication packet comprised of the URL of the ARS 308, the keystroke automator ID and the user ID. If another type of communications program were utilized, then it would have to be converted into language compatible with that program. Of course, a user could actually key in the information on the MRC 1606 and then append the appropriate intermediate routing information thereafter. As will be described hereinbelow, the intermediate routing information appended thereto is the URL of the ARS 308 disposed on the GCN 306.

As part of the configuration for using the keystroke automator 1600, the PC 302 hosts keystroke automator software which is operable to interpret data transmitted from the keystroke automator 1600, and to create a message packet having the scanned product information and keystroke automator ID, routing information, and a user ID which identifies the user location of the keystroke automator 1600. The keystroke automator software loads at boot-up of the PC 302 and runs in the background. In response to receiving a scanned MRC 1606, the wedge interface 1608 outputs a keystroke code (e.g., ALT-F10) to bring the keystroke automator program into the foreground for interaction by the operating system. The keystroke automator program then inserts the necessary information into the browser program. The message packet is then transmitted to interface 304 across the global communication network 306 to the ARS 308. The ARS 308 interrogates the message packet and performs a lookup function using the ARS database 310. If a match is found between particular parameters of the message packet, a return message packet is sent back to the PC 302 for processing.

The keystroke automator program running on PC 302 functions to partition the browser window displayed to the user into several individual areas. This is for the purpose of preparing to present to the user selected information in each of the individual areas (also called "framing"). The selected

17

information comprises the product information which the user requested by scanning the MRC 1606 using the keystroke automator 1600, information about the keystroke automator distributor which establishes the identity of the company associated with that particular keystroke automator 1600, and at least one or more other frames which may be advertisements related to other products that the keystroke automator distributor sells. Note that the advertisements displayed by the keystroke automator distributor may be related to the product of interest or totally unrelated. For example, if a user scans the MRC 1606 of a soda of Company A, the keystroke automator distributor may generate an advertisement of a new soft drink being marketed by Company A, that it sells. On the other hand, the keystroke automator distributor may also structure the display of information to the user such that a user requesting product information of a Product X may get the requested information of Product X along with advertisements for a competing item Product Y. Essentially, the keystroke automator distributor is free to generate any advertisement to the user in response to the user requesting product information.

The return message packet transmitted from the ARS 308 to the PC 302 is then transmitted back across the GCN 306 to the advertiser server 312. The advertiser server 312 restructures the message packet and appends the particular product information for transmission back to the PC 302. Upon receiving the particular advertiser information from advertiser server 312, the PC 302 then retransmits a message to the keystroke automator distributor site 1616 and E-commerce site 1618 to obtain the information that needs to be framed in the browser window displayed to the user.

Therefore, the keystroke automator 1600 is associated with the keystroke automator distributor by way of the keystroke automator ID such that scanning a product MRC 1606 in order to obtain information about that particular product generates one or more responses from one or more remote sites disposed on the GCN 306. Stored in the keystroke automator 1600 is the keystroke automator ID which establishes its relationship to the keystroke automator distributor. Proprietary keystroke automator software running on the PC 302 operates to decode scanned MRC information and the keystroke automator ID received from the keystroke automator 1600 and wedge interface 1608, and also provides a unique user ID for establishing the location of the user of the keystroke automator 1600. The keystroke automator software also assembles message packets and works in conjunction with the onboard communication software (e.g., a browser) to automatically route the message packets across the GCN 306 such that the one or more remote sites disposed on the GCN 306 return information to be framed for presentation to the user.

Referring now to FIG. 17, there is illustrated a conversion circuit of the wedge interface. A microcontroller 1700 provides conversion of the data from the keystroke automator 1600 and controls interfacing of the keyboard 1610 and keystroke automator 1600 with the PC 302. The microcontroller 1700 has contained therein a memory 1702 or it can have external memory. There are provided a plurality of keystroke automator interfaces 1704 to the keystroke automator 1600, a plurality of PC interfaces 1706 to the PC 302, and plurality of keyboard interfaces 1708 to the keyboard 1610. In general, the keystroke automator interfaces 1704 comprise a serial data line, a ground line, and a power line. Similarly, the keyboard interfaces 1708 comprise a serial data line, a ground line, a clock line, and a power line. The PC 302 provides a clock line, a power line, a serial data, and a ground line for input to the microcontroller 1700. The microcontroller 1700

18

is operable to receive signals from the keyboard 1610 and transfer the signals to the PC 302 as keyboard signals. Operation with the keyboard 1610 is essentially a "pass-through" procedure. Data output from the keyboard 1610 is already in keyboard format, and therefore requires no conversion by the wedge interface 1608. With respect to the keystroke automator 1600, the serial data is not compatible with a keyboard 1610 and, therefore, it must be converted into a keyboard format in order to allow input thereof to the keyboard input of the PC 302.

The microcontroller 1700 performs this function after decoding this MRC information, and conversion of this MRC information into an appropriate stream of data which is comprised of the MRC information and the appended URL. This appended URL will be pre-stored in the memory 1702 and is programmable at the time of manufacture. It is noted that the memory 1702 is illustrated as being contained within the microcontroller 1702 to provide a single chip solution. However, this could be external memory that is accessible by the microcontroller 1702. Therefore, the microcontroller 1700 provides an interface between the keystroke automator 1600 and the keyboard 1610 to the PC 302 which allows the keystroke automator 1600 to receive coded information and convert it to keyboard strokes or, alternatively, to merely pass-through the keystrokes from the keyboard 1610. Therefore, the user need not install any type of plug-in circuit board into the motherboard of the PC 302 in order to provide an interface to the keystroke automator 1600; rather, the user need only utilize the already available keyboard port in order to input the appropriate data into the system.

In this particular disclosed embodiment, the microcontroller 1700 comprises a PIC16C73 microcontroller by Microchip Technologies™. The PIC16C73 device is a low cost CMOS 8-bit microcontroller with an integrated analog-to-digital converter. The PIC16C73 device, as illustrated in the disclosed embodiment, has 192 bytes of RAM and 4kx4 of EPROM memory. The microcontroller 1700 can accommodate asynchronous or synchronous inputs from input devices connected to it. In this disclosed embodiment, communication to the keyboard 1610 is synchronous while it is asynchronous when communicating with keystroke automator 1600.

It should be noted that, although in this particular embodiment MRC information of the MRC 1606 is input into the keyboard input port of the PC 302, disclosed methods may also be advantageously utilized with high speed port architectures such as Universal Serial Bus ("USB") and IEEE 1394.

MRCs (e.g., bar codes) can be structured to be read in either direction. Timing considerations need to be addressed because of the variety of individuals scanning the MRC introduce a wide variety of scan rates. Bar codes use bars of varying widths. The presence of a black bar generates a positive pulse, and the absence of a black bar generates no pulse. Each character of a conventional bar code has associated therewith seven pulses or bars. Depending on the width of the bars, the time between pulses varies. In this disclosed embodiment, the interface circuitry 1608 performs a "running" calculation of the scan time based upon the rising edge of the pulses commencing with the leader or header information. The minimum and maximum scans times are calculated continuously in software with the interface 1608 during the scanning process to ensure a successful scan by the user.

Referring now to FIG. 18, there is illustrated a sample message packet transmitted from the user's PC 302 to the ARS 308. The message packet 1800 comprises a number of bits of information including the MRC information 1802 obtained from the user scanning the MRC 1606 with the

19

keystroke automator **1600**; the keystroke automator ID **1804** which is embedded in a memory in the keystroke automator **1600** and identifies it with a particular keystroke automator distributor; and a user ID **1806** which is derived from the software running on the PC **302** and which identifies uniquely with the user location. Note that the message packet includes other necessary information for the proper transmission for point to point.

Referring now to FIG. **19**, there is illustrated a more detailed block diagram of the routing of the message packets in order to present the framed information to the user. As is mentioned hereinabove, when the user scans a MRC **1606** using the keystroke automator **1600**, a keystroke automator program running on the user PC **302** is operable to interpret the information output by the keystroke automator **1600** and generate a message packet for transmission over the GCN **306**. The keystroke automator program assembles the message packet such that it is directed to the ARS **308** disposed on the GCN **306**. The message packet contains several pieces of information including the keystroke automator ID **1804** which links it to the keystroke automator distributor, the user ID **1806** which identifies the particular user using the keystroke automator **1600**, and MRC information **1802** describing a particular product of interest to the user. This message from the PC **302** is transmitted over a path **1900** to the ARS **308** where the ARS database **310** is accessed to cross reference the ID information **1804** and MRC information **1802** to a particular advertiser and keystroke automator distributor. The ARS **308** returns a message packet over a path **1902** to the user PC **302** which contains routing information as to the location of various other sites disposed on the GCN **306**, for example, the advertiser server **312** and keystroke automator distributor site **1616**.

It can be appreciated that other information can also be provided by the ARS **308** which more closely targets the particular user of the keystroke automator **1600**. For example, if it is known that a particular keystroke automator **1600** is sold in a certain geographic area, this information can be useful in targeting the particular user with certain advertising information relevant to that geographic area. In any case, the information returned from the ARS **308** over path **1902** provides enough information for the keystroke automator program running on the user PC **302** to identify a number of other sites disposed on the GCN **306**. The user PC **302** then processes the return message packet and routes another message packet over a path **1904** to the advertiser server **312**. The advertiser server **312** then returns product information of the particular product in which the user was interested back to the user PC **302** over a path **1906**. Similarly, the user PC **302** routes information (e.g., the URL of the keystroke automator distributor site and the user profile) to the keystroke automator distributor site **1616** over a path **1908** in order to obtain information back over a path **1910** for framing any banners which identify the keystroke automator distributor. Additionally, the user PC **302** forwards a message packet to the E-commerce site **1618** over a path **1912** in order to return information regarding any particular advertisements the keystroke automator distributor wants to display to the user. The advertisements are returned to the PC **302** over a path **1914**.

Referring now to FIG. **20**, there is illustrated a block diagram of a browser window according to the disclosed embodiment. The browser window **2000** is partitioned into a plurality of areas for framing specific information. A MRC area **2002** displays that product information in which the user was interested; a keystroke automator-specific area **2004** displays information about the keystroke automator distributor; and an E-commerce area **2006** displays advertising informa-

20

tion that the keystroke automator distributor selects for display according to this particular user and keystroke automator **1600**. As mentioned hereinabove, a program operable to process scanned MRC information with the unique keystroke automator **1600** develops the browser window by partitioning it into specific areas for the framing of information. Therefore, information returned from the E-commerce site **1608** is passed through the GCN **306** to the particular E-commerce frame **2006**. Similarly, information about the particular product of interest is returned from the advertiser site **312** across the GCN **306** to the particular MRC specific area **2002**. Information placed in the keystroke automator-specific area **2004** is information about the keystroke automator distributor which is returned from the keystroke automator distributor site **1616** across GCN **306**.

Referring now to FIG. **21**, there is illustrated a structure of information contained in the ARS database. The ARS database **310** contains a variety of information required to properly interrogate and assemble packets for obtaining information from the E various sites disposed on the GCN **306**. The ARS database **310** has a database structure **2100** which contains addresses for the web sites containing the product information requested by the user when scanning the MRC **1606** with the keystroke automator **1600**. Under a Product heading **2102** are listed the particular MRCs and associated routing information for addressing the respective server location. For example, the ARS server **308** may contain any number of advertisers having unique URL addresses associated therewith. Therefore, the MRC **1606** of a particular product is associated with a unique URL address which routes any request for information of that product to that particular advertiser's site. Also part of the ARS database structure **2000** is a heading of Keystroke automator **2104** under which is the keystroke automator ID **1804** and the distributor associated with that keystroke automator ID **1804**.

It can be appreciated that there may be a number of distributors using the disclosed architecture such that each distributor has an ID embedded in the keystroke automator **1600** which uniquely identifies that keystroke automator with the particular distributor. Therefore, the unique keystroke automator ID **1804** needs to be listed with the respective distributors of that keystroke automator **1600** in order to process the information that needs to be framed and displayed to that particular user. Another heading under the ARS database structure **2100** is a user heading **2106** which contains profile information associated with that particular user ID **1806**. As mentioned hereinabove, the user ID **1806** is obtained via the keystroke automator software running on the PC **302** and upon installation or subsequent configuration may request that the user input certain profile information which may be used to target that particular user with products and services which identify with that user profile. The ARS database structure **2100** also contains an E-commerce heading **2108** which contains information related to the MRC **1606** and an advertisement that may be triggered by the request for that information. For example, any MRC **1606** associated with a paper source **1602** can be associated with the specific information in the ARS database **310**.

A user wishing to obtain information about a specific soft drink may, in fact, trigger an advertising response of a competitor product. Similarly, the user interested in information about that particular soft drink may also trigger information which is relevant to that particular product or a product which may normally be served in conjunction with that soft drink. Furthermore, if the user profile indicates that this individual has significant interest in finance or insurance, the request for information regarding this particular MRC product may trig-

21

ger advertisement from an E-commerce server **1618** related to information about finance and insurance. It should be noted that the information described as contained within the ARS database structure **2100** is not limited to what has been described, but may comprise any number of pieces of information used to present desired information to the computer display of the user.

Referring now to FIG. 22, there is illustrated a flowchart of the process of receiving information from the user's perspective, and according to the disclosed embodiment. The keystroke automator software running on the user's PC **302** runs in the background until activated by output from the keystroke automator **1600**. Therefore, flow moves to a decision block **2200** where if a scanned input does not occur, flow moves out the "N" path and loops back to the input of decision block **2200**. On the other hand, if scanned input information is received, flow moves out the "Y" path to a function block **2202** where the keystroke automator software assembles a message packet containing the MRC information, the keystroke automator ID **1804** and the ARS **308** URL address. Additionally, the browser is launched in which this information is placed for transmission to the ARS **308**. Flow then moves to a function block **2204** where the browser is partitioned into any number of areas in which information is displayed when obtained from the keystroke automator distributor site **1616**, the E-commerce site **1618**, and the advertiser server **312**. It should be known that although three frames are shown in the particular window **2000** of this embodiment, the number of frames displayed in the window **2000** is limited only by the available real estate of the window **2000** area itself.

After the keystroke automator software partitions the browser window into one or more frames in preparation of receipt of return information, flow moves to a decision block **2206** where the computer waits for information to be returned from the various sites disposed on the GCN **306**. If information is not returned, flow moves out the "N" path and simply loops back to the input to continue monitoring for receipt of the information. If information has been received, flow moves out the "Y" path to a function block **2208** where routing information for each frame (or partitioned area of the window **2000**) is inserted into one or more packets for transmission to the various sites. The various sites then return the requested information back to the PC **302**, as indicated in function block **2210**. Flow is then to a function block **2212** where the proprietary software working in conjunction with the hosted browser places the returned information into the respective frames of the window. The user, viewing the display at PC **302**, then perceives a variety of information, one of which is the particular product information which he or she requested, in addition to keystroke automator distributor information, and possibly other advertisements based upon the user's profile.

Referring now to FIG. 23, there is illustrated a flowchart of the process according to the ARS. The ARS **308** is operable to decode and process messages received from the GCN **306**. Therefore, flow is to a decision block **2300** where, if MRC information is not received, flow is out the "N" path with loop-back to its input. If MRC information has been received, flow is to a function block **2302** where a matching process occurs to link the bar-coded product information to its respective manufacturer. The ARS database **310** also associates the URL address of the manufacturer's server. When a match is found, the ARS **308** begins to assemble a message packet of information for transmission back to the PC **302**, as indicated in function block **2304**. The message packet contains the product information and the URL address of the manufactur-

22

er's web site. Flow then moves to a decision block **2306** where the keystroke automator ID **1804** is compared with the list of keystroke automator IDs issued by the particular keystroke automator distributor. If the keystroke automator ID **1804** is validated, flow moves out the "Y" path to a function block **2308** where the message packet is appended with the keystroke automator ID **1804** and distributor routing address. Flow then moves to a decision block **2310** where the ARS **308** determines if any E-commerce information is to be associated with a particular keystroke automator ID **1804**. If so, flow is out the "Y" path to a function block **2312** where the message packet is appended with the E-commerce routing string. The E-commerce routing string provides addressing for the E-commerce server **1618**. Flow then moves to a function block **2314** where all message packets are returned back to the PC **302** for processing.

Referring back to decision block **2306**, if the keystroke automator ID **1804** is determined to be invalid, flow moves out the "N" path and jumps forward to the input of decision block **2314**, since the lack of a keystroke automator ID **1804** interrupts the link to any advertising provided by the E-commerce server **1618**. At this point, the only information provided is the link to the advertiser server **312** for return of product information. Referring now to decision block **2310**, if no E-commerce information is available, flow moves out the "N" path and jumps forward to the input of function block **2314** where the message packet back to the PC **302** contains only the URL of the advertiser server **312**, the MRC information, the distributor server **1616** address and keystroke automator ID **1804** information.

Referring now to FIG. 24, there is illustrated a flowchart of the process performed at the E-commerce site. The E-commerce server **1618** receives the message packet from the user PC **302**, as indicated in function block **2400**, and decodes the packet to perform a match with the MRC information. Moving on to a decision block **2402**, if the match is unsuccessful, flow is out the "N" path to a function block **2404** where the match is rejected. A message may be returned to indicate that a problem occurred and the user may need to re-scan the product MRC **1606**. If a successful match occurs, flow moves out the "Y" path to a function block **2406** where the keystroke automator ID **1804** is matched with the MRC product information. The MRC information may be distributed to customers over a large geographic area. However, the keystroke automator **1606** may be coded for certain geographic areas. For example, a keystroke automator **1600** having an XXX ID may be restricted for sale in the Southwestern United States while a keystroke automator **1600** having a YYY ID may be sold only in the Northeast. In this way, geographic areas may be targeted with advertising more appealing to that particular area. Advertising returned to the user PC **302** may be focused further by obtaining a user profile when the software or keystroke automator **1600** are installed. In this way, advertising may be focused based upon the user profile. Therefore, flow moves to a function block **2408** to lookup the E-commerce action based upon the keystroke automator ID **1804** and the MRC information. Flow moves to a function block **2410** to assemble all the information into a packet for return to the user PC **302**. The product information and/or user profile information may be returned. Flow is then to a function block **2412** where the message packet is transmitted.

Passive Transponder

Referring now to FIG. 25, there is illustrated a passive transponder system according to a disclosed embodiment. In general, when the object having the transponder is brought within range of a computer (i.e., a network interface device) to communicate thereto, one or more unique codes (UCs) and

23

a unique transponder identification code (UTID) embedded within the transponder are communicated to the computer in response to the computer activating the transponder, to cause network-based information corresponding to the one or more UCs to be retrieved and presented to the user. The signal transmitted to the computer may be communicated via a number of mechanisms including a radio frequency (RF) signal, an infrared signal or any other conventional communication protocols, or an audio signal. To prevent the undesirable download of stored UCs to a foreign system (i.e., not a computer system of the user) which the user passes in close proximity thereto, a handshaking scheme between the transponder and the computer may be employed to ensure that the foreign system is not controlled by the object of the user simply walking past the foreign system.

More particularly, a user carries an object **2500** which contains a passive transponder **2502**. When desired, the user brings the object **2500** within range of the PC **302** to be activated for the automatic and substantially immediate retrieval of network-based information. The PC **302** has connected thereto a transmitter **2504** for activating the transponder **2502** of the object **2500**, and a receiver **2506** for receiving signals received therefrom once the object **2500** has been activated. Therefore, when the user brings the object **2500** within the transmitting range of the transmitter **2504**, a signal is transmitted to the object **2500** to energize the transponder **2502**. In response thereto, the transponder **2502** accesses one or more of the stored UCs and the UTID, which UCs and the UTID are then modulated onto a signal and transmitted to the receiver **2506** which is connected to the PC **302**. The PC **302** then receives the signal carrying the UCs and the UTID and extracts the UCs and the UTID therefrom. The PC **302** assembles a message packet having the UCs and the UTID, and appends routing information thereto, which routing information is a network address of the ARS **308** on the GCN **306**. The message packet is transmitted through the interface **304** across the GCN **306** to the ARS **308**.

The ARS **308** then extracts the UC from the message packet (only one UC is serviced at any one time) sent from the PC **302** in order to perform a matching operation on the ARS database **310**. Associated with the UC and stored on the ARS database **310**, is the URL network address of the advertiser server **312**, also disposed on the GCN **306**. When a successful match of the UC occurs, the ARS **308** returns the associated URL network address of the advertiser server **312** back across the GCN **306** to the PC **302**. The PC **302**, running a communication application throughout this whole process, processes the returned advertiser server **312** URL network address and connects the PC **302** across the GCN **306** to the advertiser server **312**. The URL network address of the advertiser server **312** obtained from the ARS database contains the direct path information for the information associated with the UC, such that the information corresponding to the UC can be obtained directly from a database **2508** associated with the advertiser server **312**. The information associated with the UC is then returned from the advertiser server across the GCN **306** to the PC **302** where it can, for example, be presented to the user via the display **1612**.

It can be appreciated that the information returned from the database **2508** of the advertiser server **312** can also be in the form of audio information which would be transmitted back across the GCN **306** to the PC **302** and played to the user using the multimedia audio system of the PC **302**. The PC **302** has the local database **1614** attached thereto to store operating system software and other programs for normal operation of the PC **302**. The keyboard **1610** provides manual input by the

24

user for operating and controlling the PC and interacting with various programs of the PC **302**.

In operation, the transponder **2502** is similar to that associated with passive "tags" that utilize an inductive element that is operable to receive a low frequency power signal, use that power signal via a detection circuit to charge up a capacitor which will then power an on-board chip. This chip, once powered up, will then transmit out an identification code via a separate antenna or transmission circuit or, in most embodiments of these type of conventional devices, transmit the code back through the inductive element. These are conventional systems, which are described in detail in U.S. Pat. No. 4,333,072, which is incorporated herein by reference. These transponders are completely "passive" in that they will be read when they are in proximity to the sensing terminal.

As described hereinabove, the UC is stored in the transponder **2502** as a permanent value. This basically defines the type of card or transponder that is to be associated with the object. This could be any type of code, but it is typically standardized with respect to the type of transponder **2502**. For example, this could be associated with a "smart card" provided to a customer of a store, such that whenever a customer was in the store, their passing by a kiosk could activate a display without intervention of the user. The code would then define the type of card that was provided to the user. This could be a general transaction-type card or it could be associated with a particular type of transaction. For example, if the store were providing some type of promotion, it would provide the user that was associated with that promotion certain access rights to the possession of such transponder **2502** and the associated object **2500**, the associated object **2500** being the card in this example.

In addition to providing the UC, which represents the type of transaction, i.e., the promotion, there will also be provided the UTID which represents the particular card itself. This can be associated with the user when the user is provided such object **2500** through some type of input operation that will allow a store clerk, for example, to input information about the user in order to allow the user access to the object **2500**. Therefore, whenever a user passes a kiosk, the system, via the ARS **308**, will immediately be provided with information about the type of transaction that is to be facilitated through receipt of the UC, and also information about the user, which is associated with the UTID.

In some embodiments, the network interface device (e.g., the PC **302**) activating the transponder **2502** is provided with a unique interface identification code (UIID) distinguishing it from similar interface devices on the same system. For example, a retail establishment may include kiosks in many different departments, each kiosk having a PC **302** capable of interrogating the transponder **2502** to obtain the UCs and UTID. By providing each PC **302** with a different UIID, the particular kiosk which has been approached by the user carrying the object **2500** can be identified (e.g., to determine whether the user is approaching a kiosk in the sporting goods department or a kiosk in the cosmetics department). The PC **302** in this embodiment assembles the UIID into the message packet with the UCs and UTID transmitted through the GCN **306** to the ARS **308**.

Referring now to FIG. 26, there is illustrated an alternative embodiment where the information that resided formerly on the ARS database **310** in FIG. 25 now resides on the local database **1614** connected to the PC **302**. In this particular embodiment, activation of the object **2500** occurs substantially similar to that disclosed in FIG. 25, wherein when the user brings the object **2500** within range of the communication system of PC **302**, the transmitter **2504** transmits a signal

25

to the transponder **2502** contained on or in the object **2500** such that the transponder becomes activated and responds by transmitting the UCs and UTID by a signal to the receiver **2506** connected to the PC **302**. In response thereto, the PC **302** extracts the UC and the UTID from the receive signal of the object **2500** and performs the matching operation on the local database **1614**. When a successful match occurs, the returned information is the URL network address of the advertiser server **312** disposed on the GCN **306**. The PC **302** then running a communication package (e.g., a browser) connects the PC **302** through the interface **304** across the GCN **306** to the advertiser server **312**. The advertiser server having the database **2508** connected thereto retrieves the web page information associated with the URL network address obtained from the PC **302**, and returns the web page information back across the GCN **306** for presentation to the user at the PC **302**, for example, via the display **1612**. As mentioned hereinabove, the information returned from the advertiser server can also be in the form of audio information such that received audio information at the PC **302** is then played to the user using the PC **302** multimedia speaker system.

Referring now to FIG. **27**, there is a flowchart illustrating the process of routing the information to the ARS. Flow begins at a Start point and moves to a function block **2700** where the user brings the object **2500** within range of the PC transmitter/receiver system (**2504** and **2506**). The PC then pulses the object **2500** by transmitting a signal via the transmitter **2504**. In response thereto, the transponder **2502** on the object **2500** becomes activated and automatically retrieves the one or more UCs and UTID from an onboard memory, which one or more UCs and UTID get modulated onto a carrier and transmitted to the receiver **2506** connected to the PC **302**, as indicated in a function block **2704**. Flow is then to a function block **2706** where the PC **302** extracts the one or more UCs and UTID from the received signal, and appends routing information thereto, which routing information is the URL network address of the advertiser server **312** disposed on the GCN **306**, and more particularly, the data path to the information corresponding to the respective UC. If the PC **302** has a UIID, then this may also be appended to the UCs and UTID. The UCs and UTID (and UIID, if present) are then transmitted to the ARS **308** as indicated in function block **2702**. After receipt by the ARS **308**, a matching operation is performed on the ARS database **310**, as indicated in a function block **2708**.

Flow is then to a decision block **2710** where a matching operation is performed. If a successful match does not occur, flow is out the "N" path to a function block **2712** where a message is returned to the user that a match was unsuccessful and other action is required. On the other hand, if a successful match does occur, flow is out the "Y" path to a function block **2714** where the corresponding URL address for the advertiser server **312** is then returned back to the PC **302**. Flow is then to a function block **2716** where the communication package running on the PC **302** then connects to the advertiser server **312** in accordance with the returned URL network address from the ARS **308**. The returned network address has such detail in it that it is the address of a web page located on the database **2508** of the advertiser server **312** which contains the information corresponding to the UC contained within the transponder **2502**. This information is then returned from the advertiser server **312** across the GCN **306** to the PC **302** for presentation to the user via, for example, display **1612**. As mentioned hereinabove, the information returned from the advertiser server **312** can also be in the form of audio information which is then returned to the PC **302** and played to the user via the PC audio system. Flow is then to a Stop point.

26

Referring now to FIG. **28**, there is illustrated a flowchart of the process according to FIG. **26**. Flow begins at a Start point and moves to a function block **2800** where the user brings the object **2500** within range of the transmitter/receiver system (**2504** and **2506**) of PC **302**. Flow is then to a function block **2802** where the PC **302** pulses the object **2500** by transmitting a signal via the transmitter **2504** to the object **2502**. In response thereto, the object **2502** becomes activated and transmits the UCs and UTID within a signal to the receiver **2506** connected to the PC **302**, as indicated in a function block **2804**. Flow is then to a function block **2806** where the matching operation is performed on the local database **1614**, since in this particular embodiment, the information that was stored on the ARS database **310** in FIG. **25** is now stored on the local database **1614** of the PC **302**. Flow is then to a decision block **2808** to determine if a successful match has occurred. If not, flow is out the "N" path to a function block **2810** where a message is returned to the user indicating that the match was unsuccessful and that other action is required. On the other hand, if the match was successful, flow is out the "Y" path to a function block **2812** where the network address of the ARS **312** is returned to the PC **302**. The communication package then processes the returned network address and connects the PC **302** to the advertiser server **312** via the GCN **306**. The corresponding information of the UID is then obtained from the advertiser database **2508** and returned back across the GCN **306** to the PC **302** for presentation to the user (e.g., display **1612**), as indicated in a function block **2814**. Flow is then to a Stop point.

Referring now to FIG. **29**, there is illustrated a structure of the database. The database, whether residing on the local database storage unit **1614** of the PC **302** or of the ARS **308**, comprises at least two headings related to the UC **2900** and the network address **2902** of the advertiser server **312**. It can be appreciated that other information may also be stored in the database for the additional purpose of providing a more secure method of ensuring that the information is properly accessed. For example, the web page returned from the advertiser server **312** to the display **1612** as presented to the user may simply be a login page such that the user is then forced to provide a password and user ID prior to accessing the returned information from the advertiser server **312**. Where the object **2500** may be, for example, a smart card having the transponder **2502** attached thereto or constructed therein, and where the smart card comprises a credit card which is used to access account information, the advertiser server **312** may return the login web page to the user at the display **1612** (over a secure server connection) requiring in addition to the user name and password, a PIN (Personal Identification Number), to provide a more secure method of preventing unauthorized access to that user's personal and account information.

As described above, the database can include a large amount of information, including a UTID **2904** and/or UIID **2906**. This becomes a relational database wherein the UC **2900** may be associated with a plurality of network addresses **2902**. By using information in the UTID **2904** and/or UIID **2906**, this network address can be filtered, such that only a single network address is provided for the UC **2900**. For example, suppose that the UC were a transaction code what was associated with a particular transaction, such as a reward program in a retail establishment. It may be that the UTID **2904** differentiates a user as being a male or female and also by some age criteria. The network address is selected based upon both the transaction code embedded within the UC **2900** and also information about the user. In another example, the network address is selected based upon both the transaction

code embedded within the UC 2900 and also information regarding the current location of the user as indicated by the UIID.

Referring now to FIG. 30, there is illustrated a schematic block diagram of one embodiment of the passive transponder 2502 and of a combined transmitter/receiver unit which may be provided on PC 302 for the powering/detection of the passive transponder. It will be understood that the transponder 2502 is termed "passive" because there is no internal battery or independent power source associated therewith. In order to power the system, the passive transponder 2502 of this embodiment is provided with an inductive coupling element 3004 in the form of an inductor, which is operable to pick up an alternating wave or impulse via inductive coupling and extract the energy therein for storage in the inductive element 3004. This will create a voltage across the inductive element 3004 between a terminal 3006 and a terminal 3008. A diode 3010 is connected between the node 3008 and a node 3012, with the anode of diode 3010 connected to node 3008 and the cathode of diode 3010 connected to a node 3012. Typically, the diode 3010 will be fabricated as a Schottky diode, but can be a simple PN semiconductor diode. For the purposes of this embodiment, the PN diode will be described, although it should be understood that a Schottky diode could easily be fabricated to replace this diode. The reason for utilizing a Schottky diode is that the Schottky diode has a lower voltage drop in the forward conducting direction.

The diode 3010 is operable to rectify the voltage across the inductive element 3004 onto the node 3012, which has a capacitor 3014 disposed between node 3012 and node 3006. Node 3012 is also connected through a diode 3016 having the anode thereof connected to node 3012 and the cathode thereof connected to a node 3018 to charge up a capacitor 3020 disposed between node 3018 and 3006. The capacitor 3020 is the power supply capacitor for providing power to the passive transponder 2052. A CPU 3038 and a clock circuit 3040 are provided for providing processing and timing functions to the system. A memory 3039 is provided in communication with the CPU 3038 for storage of the UCs and the UTID of the passive transponder 2052. The CPU 3038 retrieves this information for transmittal back to the PC 302 via the transmitter/receiver unit. This retrieval is automatic when the system is powered up and is continuous as long as the system is powered. This memory 3039 is non-volatile, such as a ROM, or it could be a programmable non-volatile memory. In an alternative embodiment (not shown) a communication interface may be provided on the passive transponder 2502 such that the user can reprogram the memory 3039 with different UCs and/or UTID as necessary.

In order to communicate with the CPU 3038 for transferring data therefrom, a transmit circuit 3042 is provided for interfacing to node 3012 through a resistive element 3044. This allows RF energy to be transmitted to node 3012. It is important to note that the semiconductor junction across diode 3010 is a capacitive junction. Therefore, this will allow coupling from node 3012 to node 3008. Although not illustrated, this could actually be a tuned circuit, by selecting the value of the capacitance inherent in the design of the diode 3010. In any event, this allows an RF connection to be provided across diode 3010 while allowing sufficient energy to be input across inductive element 3004 to provide a voltage thereacross for rectification by the diode 3010 and capacitor 3014. Typically, the frequency of this connection will be in the MHz range, depending upon the design. However, many designs could be utilized. Some of these are illustrated in U.S. Pat. No. 4,333,072 by Beigel, entitled "Identification Device" issued Jun. 1, 1982, and U.S. Pat. No. 3,944,982, by Mogi et

al., and entitled "Remote Control System For Electric Apparatus" issued Mar. 16, 1982, both of which are hereby incorporated by reference. With these types of systems, power can continually be provided to the node 3012 and subsequently to capacitor 3020 to allow power to be constantly applied to the passive transponder 2052.

The transmitter/receiver unit 3048 for the PC 302 shown in the illustrated embodiment combines the functions of the remote transmitter 2504 and remote receiver 2506 previously described. The transmitter/receiver unit 3048 includes an inductive element 3050 which is operable to be disposed in an area proximate to the passive transponder 2052. The inductive element 3050 is driven by a driving circuit 3052 which provides a differential output that is driven by an oscillator 3054. This will be at a predetermined frequency and power level necessary to couple energy from inductive element 3050 to inductive element 3004. Since this is an external system, the power of the oscillator 3054 can be set to a level to account for any losses encountered in the scanning operation.

When the information is received by the transmitter/receiver unit 3048 from the passive transponder 2052, it is superimposed upon the oscillator signal driving the inductive element 3050. This is extracted therefrom via a detector 3060 which has the output thereof input to a first low pass filter 3062 and then to a second low pass filter 3064. The output of low pass filters 3062 and 3064 are compared with a comparator 3066 to provide the data. The filter 3062 will provide an average voltage output, whereas the filter 3064 will provide the actual digital voltage output. The output of the comparator 3066 is then input to a CPU 3070 which also is powered by the oscillator 3054 to process the data received therefrom. This can be input to the PC 302 connected to the transmitter/receiver unit 3048.

Although the preferred embodiment has been described in detail, it should be understood that various changes, substitutions and alterations can be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

What is claimed is:

1. A method of displaying a web page to a user who has in close association therewith a portable triggering device having a unique code stored therein and a unique portable triggering device identification code stored therein, the unique portable triggering device identification code being exclusively associated with that portable triggering device, comprising the steps of:

in response to the portable triggering device being within a predetermined proximity of an activation system, the activation system interacting with the portable triggering device causing the unique code from the triggering device to be extracted therefrom through first, activation of the portable triggering device by the activation system and then transmission of the unique code to the activation system, the activation system interfaced with a network and physically separate from the portable triggering device;

appending, to the unique code, routing information which defines the location of an intermediary location on the network such that the unique code is transmitted to the intermediary location by the activation system in accordance with the appended routing information;

retrieving location information associated with the unique code from a database at the intermediary location, the location information corresponding to a location of the web page on a remote location disposed on the network, wherein the step of retrieving location information is a

29

result of matching the unique code with the location information of the database;
 in response to retrieving the location information, automatically connecting the activation system to the remote location; and
 presenting the web page corresponding to the location information of the remote location to the user.

2. The method of claim 1, wherein the portable triggering device is a portable wireless passive transponder.

3. The method of claim 2, wherein the portable wireless passive transponder has the unique code stored therein in a non-volatile memory.

4. The method of claim 1, wherein the unique code is uniquely associated with the web page.

5. The method of claim 1, wherein the step of causing further includes causing the unique portable triggering device identification code to be extracted from the portable triggering device with the activation system.

6. The method of claim 5, wherein the step of retrieving location information further comprises the step of matching the unique code and the unique portable triggering device identification code with the location information of the database.

7. The method of claim 1, wherein the activation system comprises a transmitter and a receiver each operatively connected to a computer, the transmitter for activating the portable triggering device with an activating signal, and the receiver for receiving a triggering signal having the unique code contained therein.

8. The method of claim 1, wherein the database in the step of retrieving is local to the activation system.

9. The method of claim 1, wherein the activation system in the step of causing further includes a unique interface identification code associated with the activation system.

10. The method of claim 9, wherein the step of retrieving location information further comprises the step of appending the unique interface identification code to the unique code and transmitting it to the database.

11. The method of claim 10, wherein the step of retrieving location information further comprises the step of matching the unique code and the unique interface identification code with the location information of the database.

12. The method of claim 1, wherein the step of connecting is performed using a browser program.

13. The method of claim 1, wherein the step of presenting comprises displaying the web page to the user via a display operatively connected to the activation system.

14. An apparatus for displaying a web page to a user having a portable triggering device with a unique code stored therein and a unique portable triggering device identification code stored therein, said unique portable triggering device identification code being exclusively associated with said portable triggering device, comprising:
 an activation system disposed on a network that, when the portable triggering device is within a predetermined proximity thereof, the activation system operable to interface with the portable triggering device to cause the unique code from said triggering device to be extracted

30

therefrom in response to activation of the portable triggering device by the activation system and then transmission of the unique code to the activation system when said portable triggering device is proximate to said activation system, said activation system physically separate from said portable triggering device;
 wherein routing information which defines the location of an intermediary location on the network is appended to the unique code such that the unique code is transmitted to the intermediary location by the activation system in accordance with the routing information;
 wherein location information associated with said unique code is retrieved from a database at the intermediary location, said location information corresponding to a location of the web page on a remote location disposed on said network, wherein retrieving location information is a result of matching the unique code with the location information of the database;
 wherein in response to said location information being retrieved from said database, said activation system is automatically connected to said remote location;
 wherein the corresponding web page of said remote location is presented to the user via said activation system on a display.

15. The apparatus of claim 14, wherein said portable triggering device is a portable wireless passive transponder.

16. The apparatus of claim 15, wherein said portable wireless passive transponder has said unique code stored therein in a non-volatile memory.

17. The apparatus of claim 14, wherein said unique code is uniquely associated with the web page.

18. The apparatus of claim 14, wherein said activation system comprises a transmitter and a receiver each operatively connected to a computer, said transmitter for activating said portable triggering device with an activating signal, and said receiver for receiving a triggering signal having said unique code contained therein.

19. The apparatus of claim 18, wherein said activation system is further adapted for receiving a unique transponder identification code from said portable triggering device.

20. The apparatus of claim 14, wherein a unique transponder identification code is also matched with said location information of said database.

21. The apparatus of claim 14, wherein said activation system further includes a unique interface identification code associated with said activation system.

22. The apparatus of claim 21, wherein activation system retrieves location information corresponding to said unique code and said unique interface identification code from said database.

23. The apparatus of claim 14, wherein said activation system is connected to said remote location using a browser program.

24. The apparatus of claim 14, wherein the web page is presented to the user via a video display operatively connected to said activation system.
